INTRODUCTION

- ➤ Anemia is the most common extra-intestinal complication of inflammatory bowel diseases (IBD)
- >Anemia in IBD has been associated with worse prognosis, increased hospitalization rates, and reduced quality of life
- > Regular screening for iron deficiency anemia (IDA) and appropriate treatment is crucial for IBD patients
- ➤ Iron supplementation can be administered orally or intravenously (IV)
- ➤ The choice between oral and IV iron supplementation is still debated among physicians
- >The goal of the study was to compare the effectiveness and tolerability of oral and IV iron supplementation for treating anemia in adult IBD patients.

ANALYSIS

- > Data synthesis and statistical analysis performed using Review Manager 5.4 software
- ➤ Risk ratios (RRs) with corresponding 95% confidence intervals (95% CIs) calculated using a fixed-effect model for each outcome
- > Heterogeneity between studies measured using I2 value, with I2 ≥ 50% indicating substantial heterogeneity ➤ Relative risk (RR) and its 95% confidence intervals used for dichotomous variables ➤ Significance level set at p-value less than 0.05.

DISCUSSION

- > Iron supplementation improves quality of life and illness prognosis in IBD patients The choice between oral and intravenous (IV) iron forms is unclear
- >IV iron compounds like iron sucrose, ferric carboxymaltose, and iron isomaltoside are safe and effective >IV iron replenishes body iron reserves
- quicker and more effectively than oral iron Existing systematic reviews lack metaanalysis and recent study inclusion
- Limitations include high risk of bias in included trials and lack of cost analysis

METHODS

- > Conducted a systematic review and meta-analysis of randomized controlled trials comparing IV to oral iron for treating iron deficiency anemia in adults with IBD > Searched the databases PubMed, Web of Science, Scopus, and Cochrane Central Register of Controlled Trials until December
- > Used a fixed-effect model to obtain pooled odds ratio (OR) estimates and their 95% confidence intervals (CI).

Oral Iron

IV Iron

RESULTS

- Five trials with a total of 910 IBD patients were included in the metaanalysis
- > IV iron was found to be more effective than oral iron in increasing hemoglobin levels to ≥2.0 g/dL (OR: 1.44, 95% CI: 1.09 - 1.91, P = 0.01)
- The IV iron group had lower rates of treatment withdrawal due to adverse effects or intolerance (OR: 0.23, 95% CI: 0.12 - 0.44, P < 0.0001)
- ➤ No evidence of heterogeneity was found across all studies, but there was a significant risk of bias.

Odds Ratio

CONCLUSIONS

- >IDA significantly affects healthcare expenditures and quality of life >IV iron demonstrated higher efficacy in achieving a hemoglobin response of at least 2.0 g/dL compared to oral iron supplementation
- > Patients treated with IV iron had decreased treatment termination rates due to side effects or intolerance ➤ Available randomized studies indicate that IV iron is more effective
- and well-tolerated for treating anemia in adult IBD patients compared to oral iron supplementation.
